Neuroscientists at Barrow Neurological Institute at St. Joseph's Hospital and Medical Center have discovered a direct link between eye motions and the perception of illusion motion that solves a 200-year-old debate.

Stefan Messen, Ph.D., director of the Laboratory of Behavioral Neurophysiology, Susana Martinez-Conde, Ph.D., director of the Laboratory of Visual Neuroscience, Xiaona G. Troncoso, Ph.D., and Jorge Olmo-Millan, conducted a study based on the Enigma painting, a visual illusion in which rotational motion is seen within a stationary image. The study has been the center of a debate over whether the brain or the eye is behind the perception of illusion motion.

Dr. Martinez-Conde's laboratory recently discovered that microsaccades, a small, unconscious eye movement that occurs when humans fixate their eyes, are critical to normal vision. The team of scientists conducted the Enigma study to see if microsaccades are also behind the perception of this illusion. Based on their study, the hypothesis suggesting the illusion originates solely in the brain was ruled out.

Participants in the study observed the Enigma illusion while their eye movements were simultaneously recorded with high precision cameras. Microsaccades rates increased before the illusionary motion sped up and decreased before the motion slowed, revealing a direct link between the eye movements and the illusion.

"We have discovered that this illusion originates with eye movements and not solely the brain as previously thought," says Dr. Martinez-Conde. "The findings from this study could help design future prosthetics for patients with brain damage or brain lesions that affect the perception of motion."
